

## 5. Quantitative results

**Table 1. Speech recognition accuracy by language pair**

| Language pair     | Model                | WER           | CER           | Mean latency* |
|-------------------|----------------------|---------------|---------------|---------------|
| Kiswahili-English | Intron Sahara v2.5   | <b>0.4592</b> | 0.2559        | <b>3.08 s</b> |
| Kiswahili-English | OpenAI Whisper Turbo | 0.5074        | <b>0.1660</b> | 25.60 s       |
| Kiswahili-English | Meta MMS             | 0.7067        | 0.2759        | 12.51 s       |
| Kiswahili-English | Meta Omnilingual ASR | 0.7634        | 0.2790        | 200.80 s      |

\*Latency is observed wall-clock time, not a controlled hardware benchmark: Sahara is hosted; Whisper/MMS were local; Omnilingual ran under WSL2/Linux on CPU.

**Table 2. Downstream public-service form performance**

| Language pair     | Model                | Field exact   | Exact fields | Complete forms |
|-------------------|----------------------|---------------|--------------|----------------|
| Kiswahili-English | Intron Sahara v2.5   | 0.2500        | 24/96        | 0/24           |
| Kiswahili-English | OpenAI Whisper Turbo | <b>0.3021</b> | <b>29/96</b> | 0/24           |
| Kiswahili-English | Meta MMS             | 0.0625        | 6/96         | 0/24           |
| Kiswahili-English | Meta Omnilingual ASR | 0.0729        | 7/96         | 0/24           |

**Key result: all four systems produced 0/24 completely correct forms. This is why SautiForm is designed as an assistive workflow with editable fields, clarification and explicit human confirmation rather than autonomous administrative submission.**

## 6. Result interpretation

| Model                  | What the numbers show                                                                                                                                          |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Sahara</b>          | Best WER (0.4592) and fastest observed latency (3.08 s). It recovered 24/96 exact fields. Lower WER did not translate into the best structured-field recovery. |
| <b>Whisper Turbo</b>   | Best CER (0.1660) and strongest field exact match (29/96). WER was worse than Sahara and local CPU latency was substantially higher.                           |
| <b>Meta MMS</b>        | WER/CER were materially weaker and only 6/96 fields were exact. Its Swahili adapter is monolingual, limiting within-utterance English handling.                |
| <b>Omnilingual ASR</b> | 7/96 exact fields, highest WER/CER and the slowest observed runtime in this CPU/WSL2 setup. It remains useful as a broad multilingual open comparator.         |

WER and CER are useful diagnostics, but the downstream tables are decisive for this application: a single wrong district, occupation, household count or certificate type can make an otherwise readable transcript unsuitable as a final administrative record.

## 7. Qualitative findings: strengths and weaknesses

| Model / language                                        | Strengths                                                                                                                                        | Weaknesses / risks                                                                                                                        |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Intron Sahara v2.5</b><br><b>Kiswahili-English</b>   | Native challenge backend for the target pair; best WER; fastest observed response; hosted API reduces local model-loading burden.                | CER and field recovery trailed Whisper; 0/24 complete forms; hosted processing requires network access and appropriate user transparency. |
| <b>Whisper Turbo</b><br><b>Kiswahili-English</b>        | Best CER and strongest structured-field recovery; multilingual model handled mixed-language content better than the open monolingual comparator. | Slower local CPU inference; WER worse than Sahara; still 0/24 complete forms and therefore not safe for silent form acceptance.           |
| <b>Meta MMS Kiswahili-English</b>                       | Open model; straightforward Swahili adapter; local inference was faster than Whisper in this evaluation.                                         | The swl adapter is monolingual and does not explicitly model English switches; only 6/96 exact fields; 0/24 complete forms.               |
| <b>Meta Omnilingual ASR</b><br><b>Kiswahili-English</b> | Broad multilingual model family and an additional open comparison point.                                                                         | Highest WER/CER here; only 7/96 exact fields; 200.80 s mean latency in the tested CPU/WSL2 runtime; more complex environment.             |

## 8. Product implication

Sahara is used in the live SautiForm product because it directly supports the required Kiswahili-English code-switching pair and produced the strongest WER/latency combination in this benchmark. However, the benchmark does **not** support autonomous form completion. SautiForm therefore shows the recognised transcript, extracts only supported fields, flags missing/invalid values, allows correction, reads the structured record back and requires explicit confirmation. The current prototype performs no government submission.

## 9. Limitations and reproducibility

|                        |                                                                                                                                                                                                                                             |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Scope</b>           | The benchmark is small (24 clips; 0.06255 h), task-specific and limited to one language pair. It should not be interpreted as a general ranking of African ASR systems or as demographic fairness evidence.                                 |
| <b>Latency</b>         | Execution environments differ: Sahara is a hosted API; Whisper/MMS ran locally; Omnilingual ran under WSL2/Linux on CPU. Latency is operational evidence, not a controlled hardware comparison.                                             |
| <b>Privacy</b>         | Raw held-out audio and per-clip model outputs are not published in the public repository. Any optional public audio release should occur only where participant consent explicitly covers redistribution and the samples are de-identified. |
| <b>Reproducibility</b> | The repository contains manifest validation/freezing, model adapters, deterministic WER/CER and field metrics, the shared parser and benchmark runners. Aggregate values above are the frozen final results.                                |

## 10. Submission-ready summary

**Best WER / observed latency: Sahara (0.4592; 3.08 s) | Best CER / field recovery: Whisper Turbo (0.1660; 29/96 fields) | Complete forms: 0/24 for every model.**
